SUMMARY OF PROPOSAL (In lay terms):

There are three major areas of investigation:

- 1. Vapour Explosions. An energetic propagating vapour explosion can occur if hot and cold liquids, such as molten metal and water, are suddenly mixed. Such explosions are a hazard in the metallurgical, pulp and paper, and nuclear industries. The nature of the interaction depends on the rate of energy release which is limited by the rate at which the hot liquid fragments break up, which in turn depends on the surrounding pressure and flow fields. For low flow rates, vapour bubble growth and collapse leads to drop breakup whereas for high flow rates, the drop is directly shattered by the relative flow. The objective of the present investigation is to investigate, using flash X-ray radiography, the transition from one fragmentation mechanism to another for a molten drop in water as the ambient flow velocity is increased. The results will be used to construct a more realistic model for fragmentation which will be used in models for propagating vapour explosions which are used to resolve industrial safety issues regarding the potential for and consequences of an accidental vapour explosion.
- 2. Reactive Waves in Multiphase Media. High-speed pressure waves have been observed to propagate in liquid/gas mixtures in which one or both of the components can sustain a chemical reaction. Such waves are a concern in a variety of chemical process industries. For example, so-called "bubble detonations" have been observed to propagate in a mixture consisting of combustible bubbles in an inert liquid. The objective of this experimental investigation is to determine the critical limiting conditions for the propagation of the wave and the mechanism for the wave failure. The use of the injection of inert bubbles to suppress the wave propagation will also be investigated, together with analytical modelling using a statistical approach for a dilute bubbly liquid.
- 3. Shock Waves in Heterogeneous Media. The objective of this study is to produce a quantitative model for the propagation of shock waves in laminates consisting of rigid and compressible materials. Emphasis will be placed on accurately characterizing the rate-dependent losses within the compressible layer. The model will be validated using results in which the material is subjected to an air blast wave and will be used to design a laminate to attenuate the peak pressure and impulse of the blast wave, with application to the design of protective apparel used in explosive disposal operations.

SUMMARY OF PROPOSAL FOR PUBLIC RELEASE (Use plain language)

This plain language summary will be available to the public if your proposal is funded. Although it is not mandatory, you may choose to include your business telephone number and/or your e-mail address to facilitate contact with the public and the media about your research.

Business telephone no. (optional): (514) 398-6279

E-mail address (optional): david@mecheng.mcgill

The proposed research program includes several projects, all of which involve multiphase systems in which one or more of the phases undergoes either i) a chemical reaction or ii) a physical change of phase, usually via a self-sustained propagating wave. The projects are primarily experimental, yet supported by analytical and numerical modelling. For the projects involving multiphase chemically reacting systems, combustible solid particles are added to an energetic material to change either the amount or the rate of chemical energy release. Applications of these projects include the design of advanced fuels and propellants. In the second major area of research, systems that undergo a rapid change of phase are investigated. These systems include molten metal-water mixtures and combustible liquids containing vapour bubbles. The motivation for these projects is to mitigate hazards in the metallurgical and nuclear industries and to define safe operating procedures for the transportation of combustible liquids.

SUMMARY OF PROPOSAL FOR PUBLIC RELEASE (Use plain language.)

This plain language summary will be available to the public if your proposal is funded. Although it is not mandatory, you may choose to include your business telephone number and/or your e-mail address to facilitate contact with the public and the media about your research.

Business telephone no. (optional):

E-mail address (optional): david.frost@mcgill.ca

My proposed research program includes several projects which all involve multiphase systems (solid/gas or solid/liquid) in which typically one or more of the phases reacts chemically. The projects are primarily experimental, and supported by analytical and numerical modelling. Applications of the proposed work can be divided into three areas: i) the design of advanced ceramics and propellants using nanosized particles, ii) improved predictions of the performance of commercial explosives, and iii) the protection of structures and personnel against blast waves.

i) In the first project, nanosized metal oxide particles will be produced using a metal dust flame synthesis technique. Shock compaction of the powder will be explored with the objective of producing advanced high-strength ceramics. The combustion of nanosized metal particles with water will also be investigated, with the goal of producing an energetic propellant that is safe to handle for space propulsion applications. ii) Many commercial explosives contain added metal particles to improve the performance of the explosive

(e.g., the ability to crack and move rock). In order to predict the performance of such an explosive, it is necessary to have information regarding the ignition and combustion rate of the metal particles. The second project involves a study of particle ignition and reaction in high-speed flows characteristic of the flows that occur within the gaseous detonation products.

iii) There has been considerable interest in the last several years in the development of materials for the protection of personnel and structures against blast waves from accidental or deliberate explosions. To design a system to attenuate a high-pressure shock wave, it is necessary to have a fundamental understanding of how a shock wave propagates through a material and how the material responds when rapidly loaded. Experiments will be carried out to test the ability of combinations of rigid and novel compressible materials to mitigate the effects of a blast wave on a structure.

SUMMARY OF PROPOSAL FOR PUBLIC RELEASE (Use plain language.)

This plain language summary will be available to the public if your proposal is funded. Although it is not mandatory, you may choose to include your business telephone number and/or your e-mail address to facilitate contact with the public and the media about your research.

Business telephone no. (optional):

E-mail address (optional):

My proposed research program includes several project areas which all involve multiphase systems (solid/gas or solid/liquid) in which one or more of the phases typically reacts chemically. The projects are primarily experimental, and supported by analytical and numerical modelling. Applications of the three proposed areas of research include i) improvements to the performance of commercial explosives, ii) protection of personnel and structures against blast waves and ballistic impact, and iii) the combustion synthesis of advanced materials with unusual properties. A summary of the three research areas is as follows.

i) Many commercial explosives contain added metal particles to improve the performance of the explosive (e.g., the ability to crack and move rock). In order to predict the performance of such an explosive, it is necessary to have information regarding the motion and burning rate of the metal particles in the combustion gases and surrounding air. Lab-scale experiments will be carried out to determine the particle reaction mechanism and the dependence of particle combustion rate on the particle and flow properties.

ii) There has been considerable interest recently in Canada in the development of materials for the protection of personnel and structures against blast waves and ballistic impacts from accidental or deliberate explosions. Experiments are proposed to design and test a variety of novel rigid and compressible material combinations to mitigate the effects of a blast wave. For improved ballistic protection, materials that contain a shear-thickening fluid will be investigated under impact loading.

iii) In the final research area, nanosized metal oxide particles will be produced using a metal dust flame technique with applications to material science (e.g., high-strength ceramics). A related experiment will study the reaction between nanosized aluminum powder and water for the production of pure hydrogen gas to be used in a fuel cell. Finally, reactions in metal powder mixtures will be induced with a shock wave to generate solids with potentially new and useful properties.

Business telephone no. (optional):

E-mail address (optional):

The hazards posed by shrapnel from improvised explosive devices (IEDs) are of primary concern to the Canadian Forces. In order to meet these challenges, the continued incorporation of new materials and technologies is necessary in the development of more flexible, lightweight armour systems. The integration of Shear Thickening Fluids (STF) embedded in traditional ballistic fabrics is one such technology that could be practical. The physical characteristics of STF, which consists of fine solid particles suspended in a carrier fluid, which are advantageous for protective equipment is that the materials are field-responsive. This means that the materials will behave differently under various threats. For example, under the strain involved with normal motion, the fluids are able to flow and the armour would be flexible, however upon application of a high-strain-rate force such as a ballistic event, the materials stiffen to provide protection. This enables systems involving STF to potentially be utilized in limb protection systems for soldiers to meet contemporary shrapnel threats from IEDs. Additionally, such flexible protection systems could be of interest to police forces as well as private security personnel. The proposed research program consists of a comprehensive experimental and computational investigation of the fundamental behaviour of STF under high-strain rate dynamic loading while applying the same amplitude forces that are involved in ballistic events. The ballistic response of a variety of fluid-solid particle systems will be studied using single-stage light gas guns to determine the optimum system for protecting against ballistic impact threats. The application of STF technology to develop new field-responsive armours would be invaluable to the Canadian Forces, as well as to other security personnel.

The project addresses still unresolved fundamental issues of shock and blast wave reflections in unsteady gas flows. Such reflections can be of regular or irregular (so called Mach) types corresponding to different shock wave configurations. Transitions from one type to another may occur in the course of shock or blast wave propagation, leading to significant local changes in gasdynamic and thermodynamic parameters (pressure, temperature etc.). The changes may be desirable for some applications, or, to the contrary, result in harmful consequences. The project considers the phenomenon using different physical models and computer simulation. The main goal is to explain in detail the mechanism of transformation of one shock wave configuration into another and to get reliable quantitative data on the variation of gas parameters in the course of such transformations. The obtained results will lead to practical implications in many applied fields, such as hypersonic air-breathing engines (their inlets and nozzles), initiation of detonation, explosions and implosions, blast waves, hypervelocity impacts, high-pressure science and technology.

SUMMARY OF PROPOSAL FOR PUBLIC RELEASE (Use plain language.)

This plain language summary will be available to the public if your proposal is funded. Although it is not mandatory, you may choose to include your business telephone number and/or your e-mail address to facilitate contact with the public and the media about your research.

Business telephone no. (optional): 1 (514) 398-4382

E-mail address (optional):evgeny.timofeev@mcgill.ca

The research program is concerned with essentially unsteady high-speed multi-dimensional compressible flows, which are much less explored in compressible fluid dynamics than steady phenomena and, likewise, accurate and efficient numerical methods and codes for them are few in number. New numerical methods and computer codes specifically tailored for unsteady, multi-scale, multi-fluid flows with spatially-localized features (shock waves, contact surfaces, boundary layers, vortices etc.) will be developed on the basis of the previous work by the principal investigator on locally adaptive unstructured finite-volume Euler (inviscid) solvers for non-reacting gas mixtures. Three major generalizations are to be undertaken: (1) For unsteady viscous flows at high Reynolds numbers in which viscosity effects are confined to shock fronts, boundary layers and separation zones, contact surfaces; (2) For mixtures of fluids with various equations of state (Tait, JWL etc.) (3) For nonlinear acoustics problems in heterogenous media. The research program will encompass the following application areas: (I) Basic studies of shock wave reflections, in particular on the influence of viscosity and heat conductivity on shock wave reflections; (II) Starting of air inlets of hypersonic air-breathing engines (scramjets), including recenlty proposed innovative techniques (diapgragm rupture, accelerative starting); (III) Flow dynamics in gas/explosive systems. (a) Channel effect problem (when an explosive layer is detonated inside a planar or axisymmetrical channel) which has many applications in mining, aerospace, high-pressure physics and other fields; (b) Different concepts of hypervelocity launchers in which the enormous energy densities of high explosives is used to accelerate projectiles to hypervelocities, which can be applied to high-speed impact tests (e.g. when testing satellite bumper shields); (IV) Non-linear waves in heterogenous media. In this area the developed computational method will be used for simulations of wave phase conjugation in acoustics with practical applications in echography of biological tissues, non-destructive testing, magneto-acoustics etc.

SUMMARY OF PROPOSAL FOR PUBLIC RELEASE (Use plain language.)

This plain language summary will be available to the public if your proposal is funded. Although it is not mandatory, you may choose to include your business telephone number and/or your e-mail address to facilitate contact with the public and the media about your research.

Business telephone no. (optional): 1 (514) 398-6297

E-mail address (optional): andrew.higgins@mcgill.ca

The proposed instrument to be acquired is a Photonic Doppler Velocimeter (PDV), used to obtain extremely accurate material velocity histories along two axes in high speed ballistic impact and shock wave experiments. The ability to generate this type of high quality velocity history data is essential to McGill University's continued participation in state-of-the-art research in the fields of ballistic protection, shock wave physics, and detonics. With the development of numerical modeling over the past decade, continuous data sources are necessary for the validation of new models. Experimental work involving discrete "time of arrival" data collection is now considered to be obsolete by researchers in the field. The ability to continuously record the material velocity history in an experiment will permit insights into a number of important problems. In particular, this program will use the system in evaluating novel ceramic-metal composite and shear thickening fluid armours, in simulating hypervelocity impacts caused by orbital debris, and in studying nonideal detonation propagation in commercial blasting explosives. The ability to study these processes in a high-resolution, continuous history measurement will permit models and computer simulations to be validated, which in turn can be used to predict and improve how these processes occur in applications.

Les débris orbitaux représentent une menace persistante pour toutes les activités spatiales. Afin d'être en mesure d'évaluer ce danger, il est nécessaire d'effectuer des simulations d'impacts à haute vitesse sur des structures spatiales en laboratoire et au moyen d'outils numériques. De nouveaux matériaux doivent également être testés pour évaluer leurs capacités à résister aux impacts de débris orbitaux. Ce projet développera de nouveaux outils numériques capables de résoudre l'intégralité du problème lié aux débris orbitaux. Ce modèle numérique sera notamment utilisé pour étudier les interactions entre les éléments explosifs, métalliques et gazeux. Ce modèle sera également validé et utilisé pour développer un lanceur hyper-vitesse utilisant des moyens explosifs pour générer de très hautes vitesses essentielles à l'étude de simulations d'impacts en milieu de laboratoire. Ce lanceur sera utilisé pour tester les propriétés de matériaux composites avancés qui auront le potentiel de maintenir leurs propriétés mécaniques suite à un impact. Finalement, les impacts de projectiles sur ces composites seront modélisés aux travers de calculs numériques avancés qui seront comparés aux impacts effectués en laboratoire au moyen du lanceur hyper-vitesse. Les résultats de ce projet fourniront les outils nécessaires aux entreprises québécoise, canadienne et internationales du domaine aérospatiale pour tester et effectuer des simulations sur la menace des débris orbitaux.

CSA Class Grant and Contribution Program to Support Research, Awareness and Learning in Space Science and Technology

Application Form - Research Component

Notice to Applicants: Please read the CSA Class Grant and Contribution Program Overview and the Sub-Component Applicant's Guide In full before completing this application form. These documents are available on the CSA Web site under Grants and Contribution tab. You must answer all fields as indicated. Your application may not be considered if there is missing or incomplete information. It is the applicant's responsibility to ensure that the application complies with all relevant federal, provincial/territorial and municipal laws.

CSA Class Grant and Contribution Program to Support Research, Awareness and Learning in Space Science and Technology

Application Form - Research Component

SECTION 4 - PROJECT DETAILS

Please provide a short (maximum 100 words), summary of the proposal using non-technical language suitable for public release.

This project will study how waves of chemical reaction spread through a media that is made of point-like sources, which is often encountered in nature and technological applications, but is difficult to study due to gravity-induced settling of the particles and buoyancy disrupting the wave. This study will utilize the reduced-gravity environment on a sounding rocket to study reactive wave propagation (flames) in iron powder clouds under ideal conditions. The sounding rocket flight is being provided by the ESA. The portion of the project described here to be funded by the CSA will focus on development of the models required to interpret the experimental results and testing onboard parabolic flight alreraft to further develop the experimental concept prior to the rocket flight. The result will be the experimental confirmation of a discrete regime of reactive wave propagation, a phenomenon that is also expected to occur in a other disciplines (biology, solid state physics, etc.). The improved understanding of metal combustion will have application to the use of extraterrestrial resources as propellants and to the use of metals as zero-emission energy carriers on earth.

Please describe the project using keywords (maximum 10) separated by semi-colons

reactive waves, combustion, percolation, microgravity, dust combustion, flames, heterogeneous media, discrete

Please specify the area of expertise combustion, nonlinear waves

Detailed Project Description

Please attach a detailed description of the proposed research plan, including objectives, methodology and an explanation of the role and responsibilities of each person implicated in the proposed research Project. Please structure this section with subheadings corresponding to the Evaluation Criteria presented in the Sub-Component description within which your Project is submitted.

The cover page of the attachment must contain the title of the proposal, the name of the principal investigator and the legal name of the organisation requesting the grant or contribution. Please limit the document to a maximum of 20 pages in a commonly used format (.DOC, .DOCX, .PDF, .RTF, .TXT), 12pt type face, letter sized paper and 1" margins.

SECTION 5 - PRINCIPAL INVESTIGATOR AND CO-INVESTIGATORS

Please provide below the names and coordinates of co-investigators. Please complete and attach the Natural Sciences and Engineering Research Council of Canada (NSERC) Personal Data Form (Form 100) for each investigator.

SECTION 6 - DETAILED IMPLEMENTATION SCHEDULE

Please attach a detailed implementation schedule for the proposal. CSA recommends presenting the schedule in both a Gantt Chart and a tabular format with the following column headings: Work Breakdown Structure (WBS) identifiers (Ex. 3.5.7), task name, task duration, start date, finish date, task dependencies (predecessor and successor task identifiers with, relationship type, and lead or lag durations), and assigned leads for main task groups.

SECTION 7 - DETAILED BUDGET AND SOURCES OF FUNDING

Please attach a detailed Itemised budget in a common format indicating all sources of funding and expenditures of the project.

- Information should be allocated in accordance with government fiscal years (from April 1 to March 31)
- All funding sources and all expenditures must be included, and identified as cash or in kind
- For each expenditure, the total amount, and the breakdown by source of funding must be provided

Please refer to the Sub-Component Applicant's gulde on the CSA website for a list of eligible CSA funding categories.

Electronic Receipt

Your proposal has been submitted on 9/14/2010 1:37:51 PM.

Technical Abstract (Limit your abstract to 200 words with no classified or proprietary information)

To neutralize biological warfare agents released into a plume we propose the use of the combustion of large-scale dust clouds of inorganic solid fuels including light metals and sulfur. The combustion of light metals such as Ai, Mg, Ti, Zr, and their alloys provide the following mutually complementary mechanisms for bio-agent defeat: a) heating of large air volumes to high temperatures, b) strong thermal and potential UV radiation fluxes, c)generation of biologically-active nano-oxide particles, and d) generation of active disinfectant elements (e.g.,molecular lodine) due to thermal decomposition of additives. The combustion of sulfur clouds is promising for agent neutralization due to the generation of a cloud of droplets of the strong antimicrobial agent sulfuric acid. The proposed scope of work aims to build on our basic understanding of the fundamental properties of propagating large-scale dust flames, while simultaneously experimentally verifying this approach for the intended application. Three research directions will be pursued, including investigating () the hydrodynamics of dust dispersion, ii) flame speed and flame propagation limits, and iii) the radiative properties of burning dust clouds. The experimental data collected will be used to validate multiphase models for dust combustion.

List a maximum of 8 Key Words or phrases, separated by commas, that describe the Project.

Dust cloud combustion, dust dispersal, flame speed, flame propagation limits, multiphase modeling, UV radiation flux, nano-oxide particles, lodine disinfectant
